## Global Variables in Node.js

Global variable can be accessed anywhere in the project.

Global variables can be initialized with a value and that value can be changed.

Regular variable can be accessed anywhere in the file.

Global variable can be defined by global object as below.

```
<%  
global.globalVariable = "This can be accessed anywhere!";  
console.log(globalVariable); // Output: "This can be accessed anywhere!"  
%>
```

if you set the **'use strict'** directive, Node will disable implicit globals and you will likely end up with an error at runtime rather than a working script.
