

# Laravel - Middleware

Topics : [Laravel](#)

Written on [December 21, 2023](#)

In Laravel, middleware acts as a filter for HTTP requests entering your application. It can perform various tasks such as authentication, logging, modifying request or response data, and more. Middleware is executed in a sequential manner, and you can apply it globally to all routes, to specific routes, or within a controller.

Here's a basic overview of how middleware works in Laravel:

## Creating Middleware:

You can create a middleware using the artisan command:

```
php artisan make:middleware MyMiddleware
```

This will create a new middleware class in the `app/Http/Middleware` directory.

## Middleware Structure:

A middleware class in Laravel typically contains a `handle` method. This method is called for each incoming HTTP request. Here's a simple example:

```
namespace App\Http\Middleware;

use Closure;

class MyMiddleware
{
    public function handle($request, Closure $next)
    {
        // Perform actions before the request is handled by the application.

        $response = $next($request);

        // Perform actions after the request is handled by the application.

        return $response;
    }
}
```

## Registering Middleware:

You can register middleware in the `app/Http/Kernel.php` file. The `$middleware` property contains a list of middleware that will be run on every request:

```
protected $middleware = [  
    // ...  
    \App\Http\Middleware\MyMiddleware::class,  
];
```

You can also apply middleware to specific routes in the `web.php` or `api.php` route files:

```
Route::get('/example', function () {  
    // Your route logic here  
})->middleware('my_middleware');
```

## Middleware Parameters:

You can pass parameters to middleware if needed. Modify the `handle` method to accept additional parameters:

```
public function handle($request, Closure $next, $parameter)  
{  
    // Access the parameter here.  
    // ...  
}
```

And in the `web.php` or `api.php` file, you can pass parameters like this:

```
Route::get('/example', function () {  
    // Your route logic here  
})->middleware('my_middleware:param_value');
```

## Global Middleware:

Global middleware is run on every HTTP request to your application. You can add them to the `$middleware` property in the `Kernel` class.

## Terminable Middleware:

If you need to perform actions after the response has been sent to the browser, you can implement the `TerminableMiddleware` interface and add the `terminate` method to your middleware.

```
public function terminate($request, $response)  
{  
    // Perform actions after the response is sent.  
}
```
